

# Introduction to Computational Techniques in Physics/Data Science Applications in Physics

Physics 77/88, Spring 2020

**Lecture 7: Monte Carlo Techniques**

Prof. Heather M. Gray

Many thanks to Yury Kolomensky for material used in this course

# Outline

- Introduction
- Random number generators
- Random number distributions
- Applications: integration

# Monte Carlo Simulation

- technique
  - Applicable when an or
  - Applicable when the problem has
    - e.g. an of a
  - Involves repeated obtain approximate (usually of the ) result to
- Applications
  - Most
  - Engineering, finance:
  - 
  - And of course,

# Examples

- Let's start with some examples in the python notebook

From: <https://en.wikipedia.org/wiki/Dice>

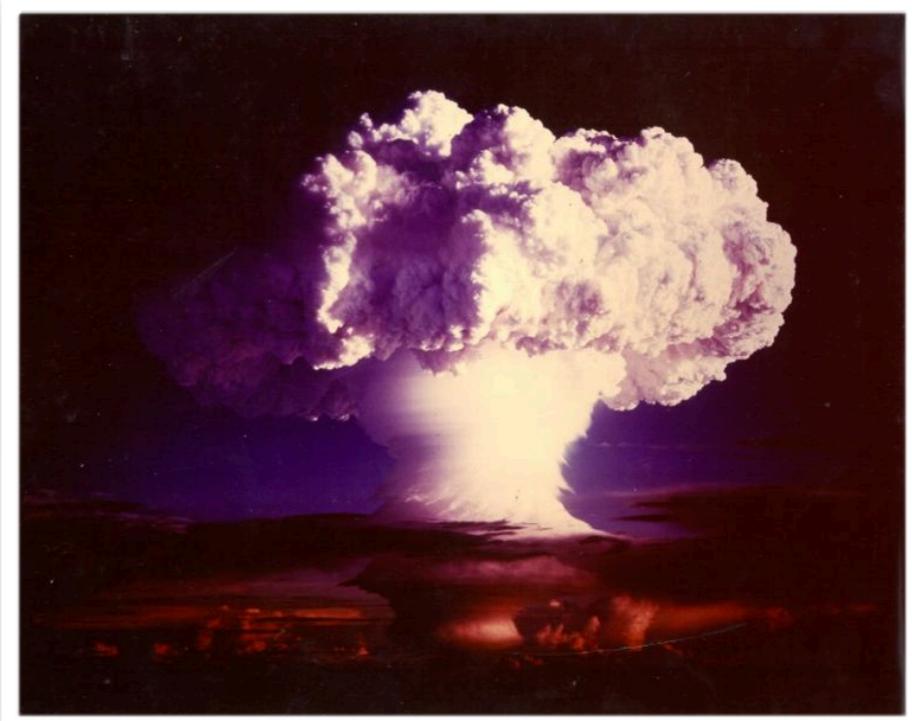

From: [https://en.wikipedia.org/wiki/Coin\\_flipping#/media/File:Coin\\_Toss\\_\(3635981474\).jpg](https://en.wikipedia.org/wiki/Coin_flipping#/media/File:Coin_Toss_(3635981474).jpg)

From: <https://en.wikipedia.org/wiki/File:AcetoFive.JPG>

# More examples

- Professional packages
  - Particle physics:
    - JETSET
    - Pythia
    - GEANT
  - Many ray-tracing/optics packages
  - First (documented) use: Manhattan project
- Possible Final Projects
  - Tournament simulator (e.g. March Madness, NHL playoffs, etc)
  - Program a game (
    - Incorporate some
      - e.g. betting odds, strategy)

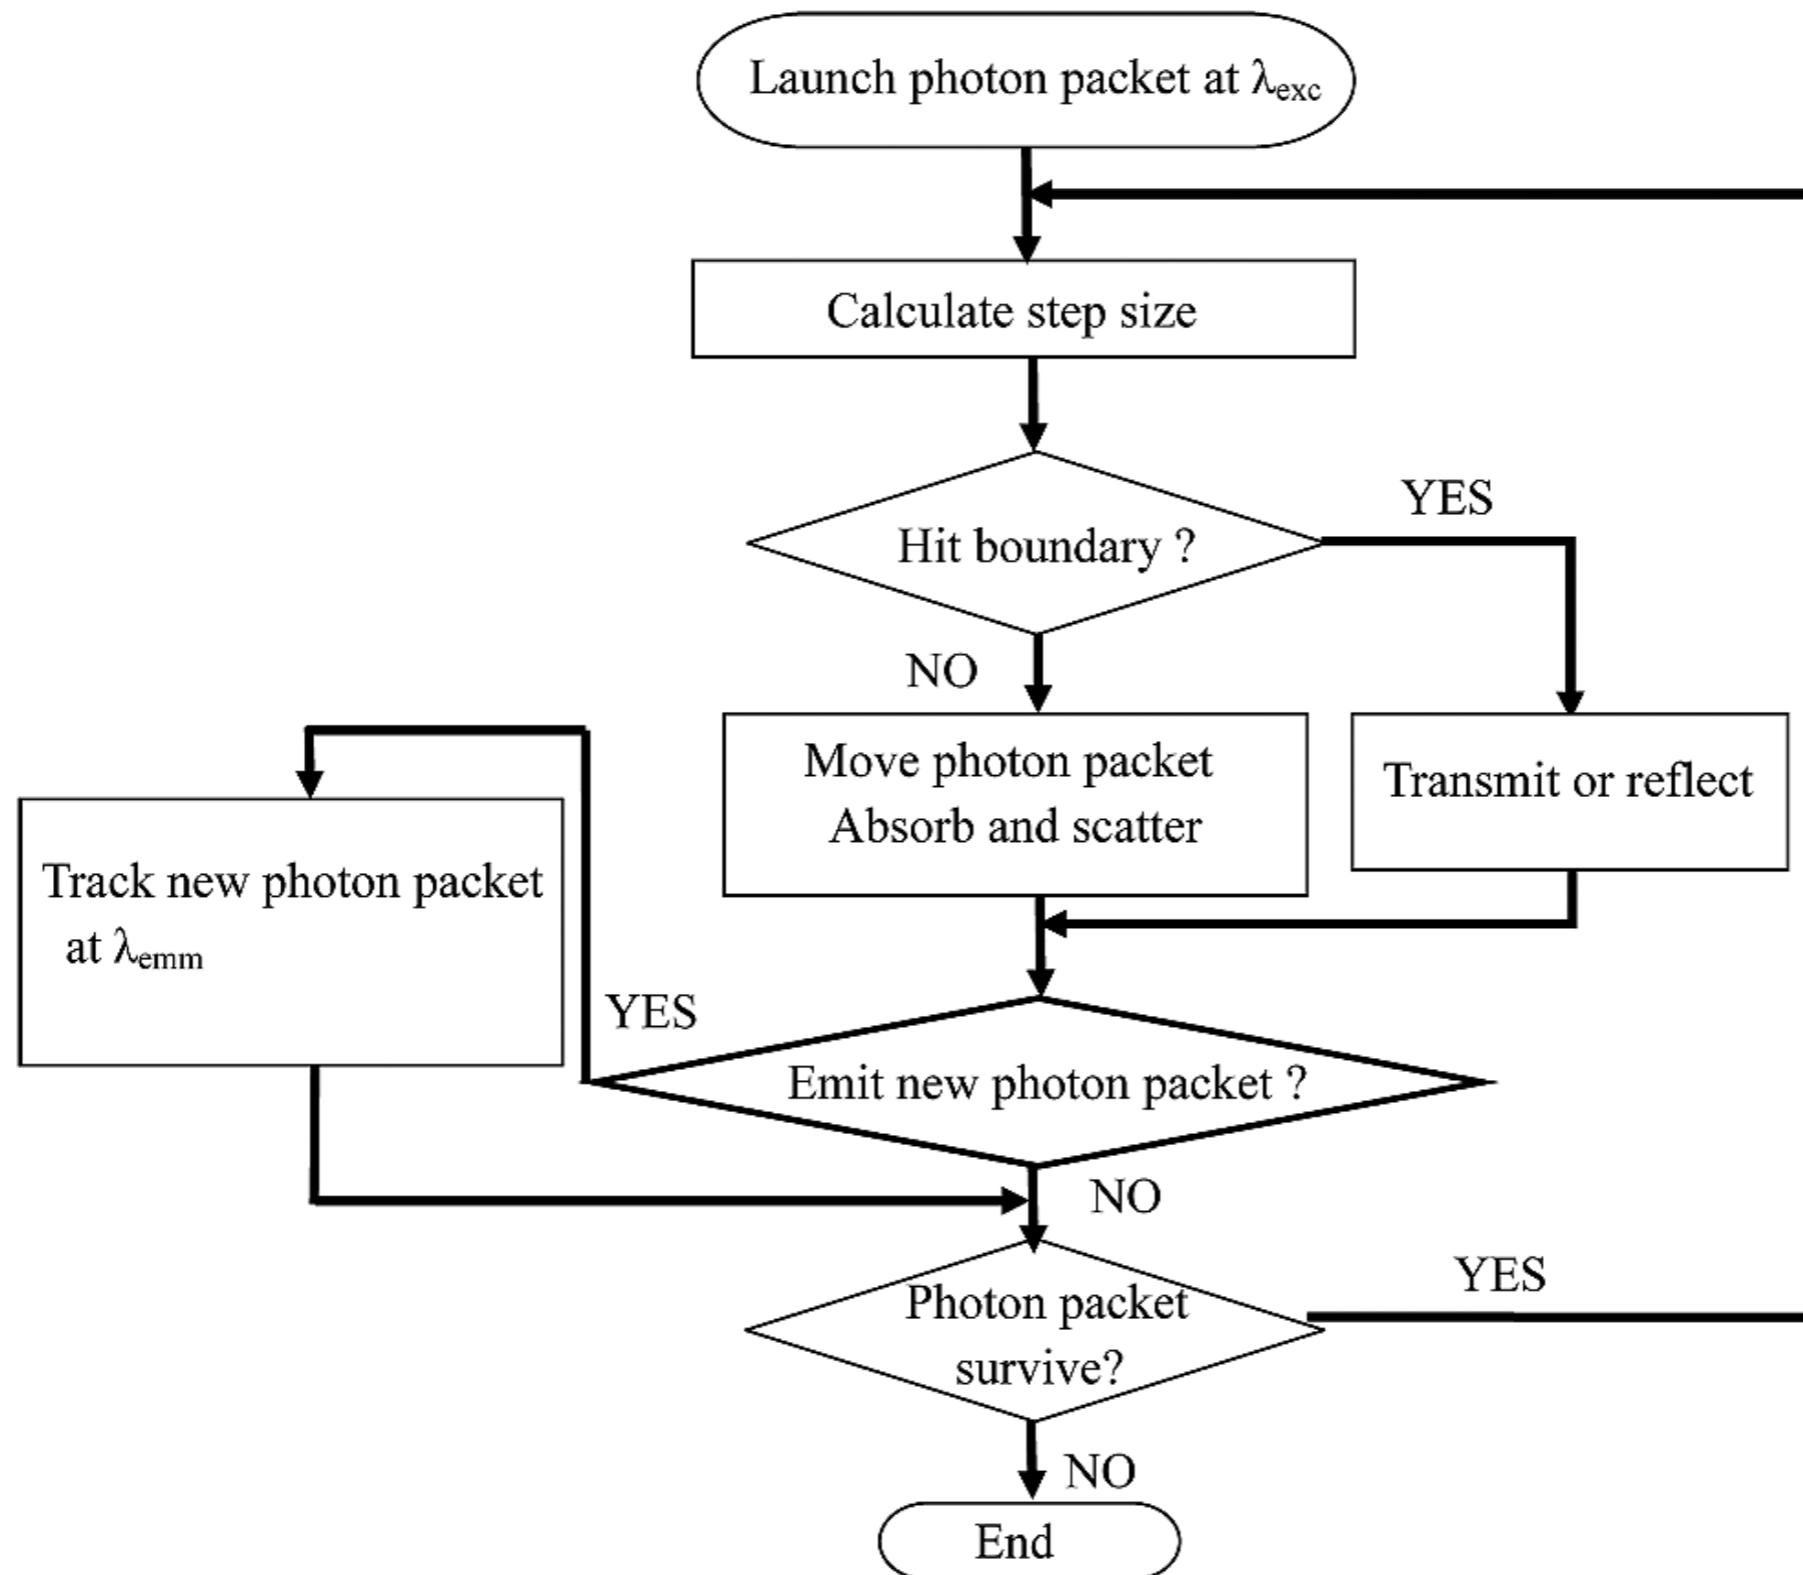

# The Monte Carlo Technique

- What Monte Carlo simulation can not do:
    - Predict of a (measurement, process, ...) or of
  - What Monte Carlo simulation can do:
    - Compute for a outcome
    - Determine probability , correlations between , ... that resemble those observed in the
  - Precision limited by:
    - sampling ( )
    - Modeling of the
      - e.g. in describing (systematics)

# Overview of the technique

- Split the process into functions , such that probability density for each could be
- For each step:
  - Identify and their
  - Generate
  - Evaluate outcome of the step
- Repeat for the
- At the end,
- Repeat , build up a of

# Example

C. Zhu and Q. Liu, "Review of Monte Carlo modeling of light transport in tissues"  
J. Biomed. Opt. 18(5), 050902 (May 10, 2013). doi:10.1117/1.JBO.18.5.050902

# Random Number Generators

- All MC simulations rely on a
  - Computer , so not
  - Although generators are possible (e.g. Johnson's noise generator — a cute ILLA project)
- The most basic distribution is
  - distributions can be by a transform of a distribution (see below)
- Requirements:
  - Generate with a very long
  - Small within the
  - “Seeded” to produce
  -

# Simplest: Linear Congruent Generator

- $x_{n+1} =$
- fixed by
- depends on
- of at most
  - So make c , a & b
  - E.g. RANDU: a= b= , c=
    - Period of numbers
    - Produces random numbers within the
- Modern generator: Mersenne Twister
  - Implemented in Python, ROOT (TRandom3)
    - Period of

- Back to the jupyter notebook

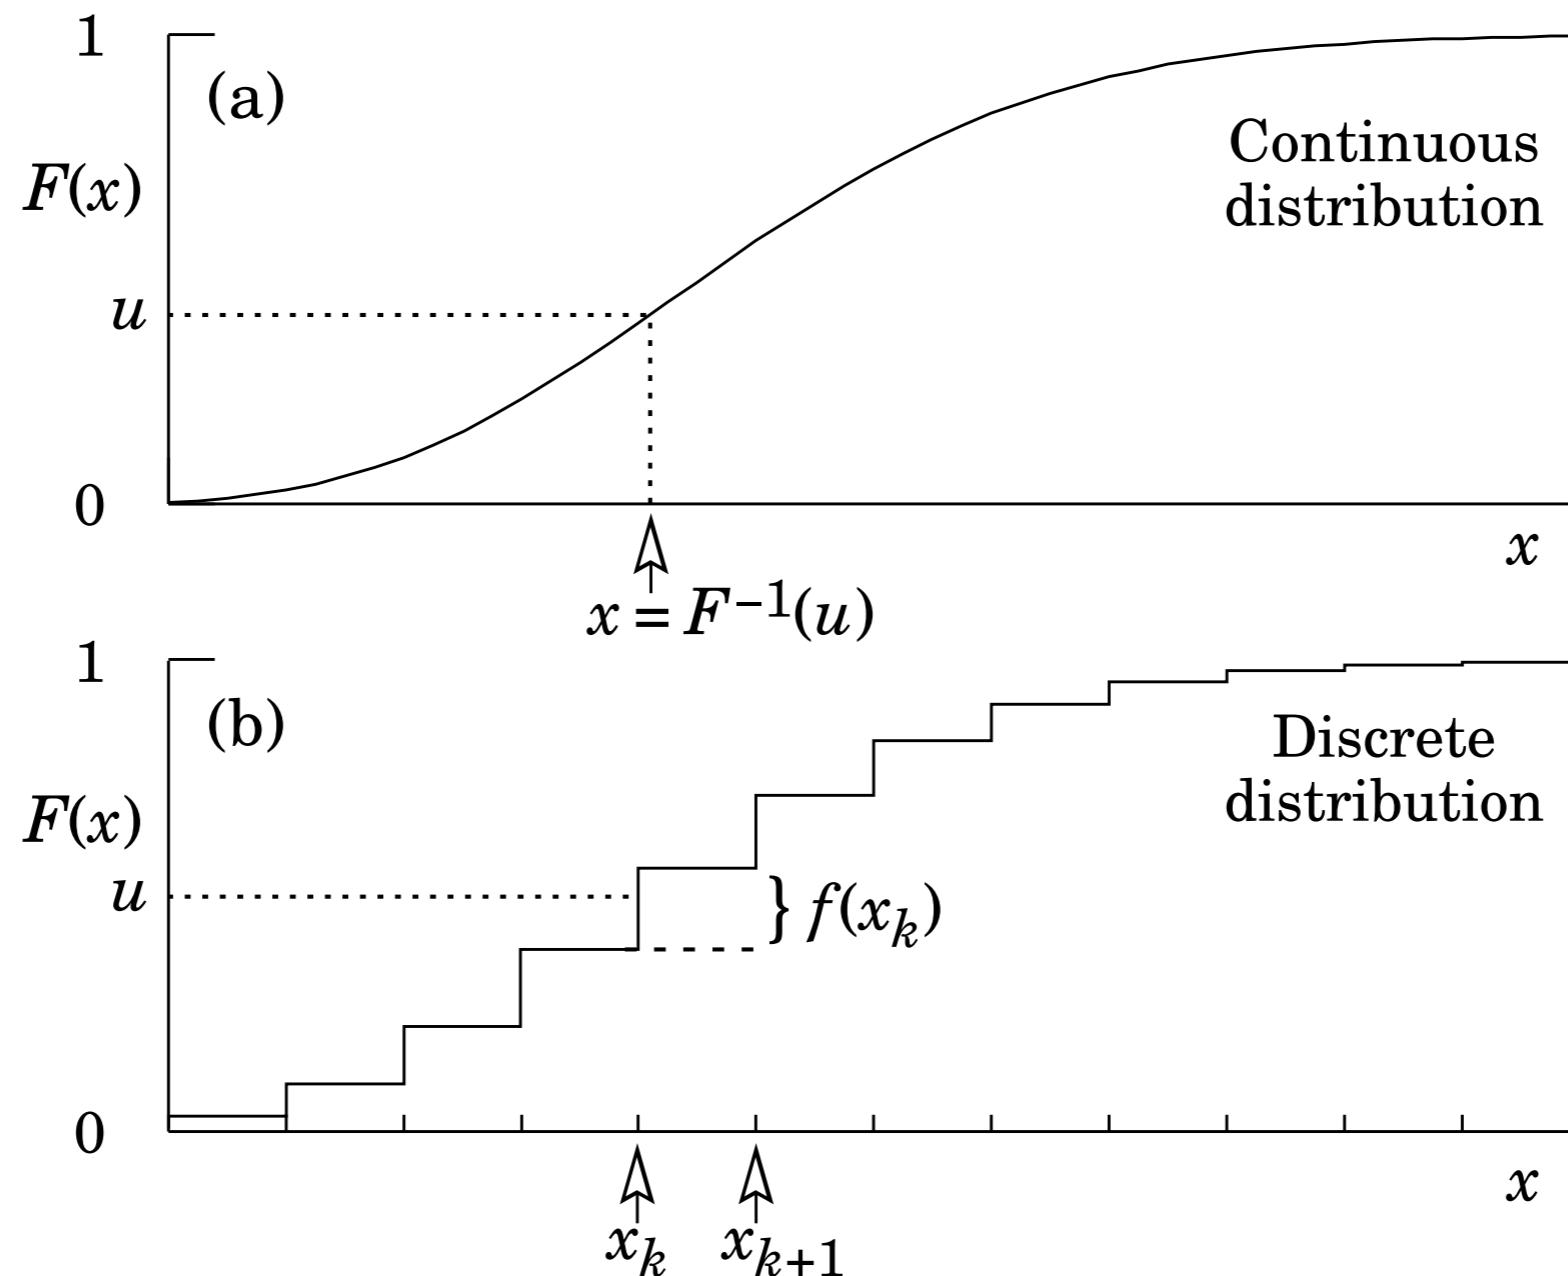

# Generating Arbitrary Distributions

- Most frequently, you want a distribution distributed according to some (predefined)
- Since most have a random number generator, derive random number from a random number :
  -
- Two basic techniques
  - method
  - von Neumann's method

# Inverse Transform Method

- Theorem:
  - If  $u$  is chosen with  $U \sim U(0, 1)$ , and  $x$  is a random variable of  $f(x)$ , then  $x = F^{-1}(u)$  is a random variable distributed between  $[a, b]$
  - $F(a) = P(X \leq a) = \int_{-\infty}^a f(x) dx$
- Therefore can implement  $x = F^{-1}(u)$  with C++:
- Generate  $u$ :
  - $u \in [0, 1], f(u) =$
  - Invert  $F^{-1}$ :
  - $x =$

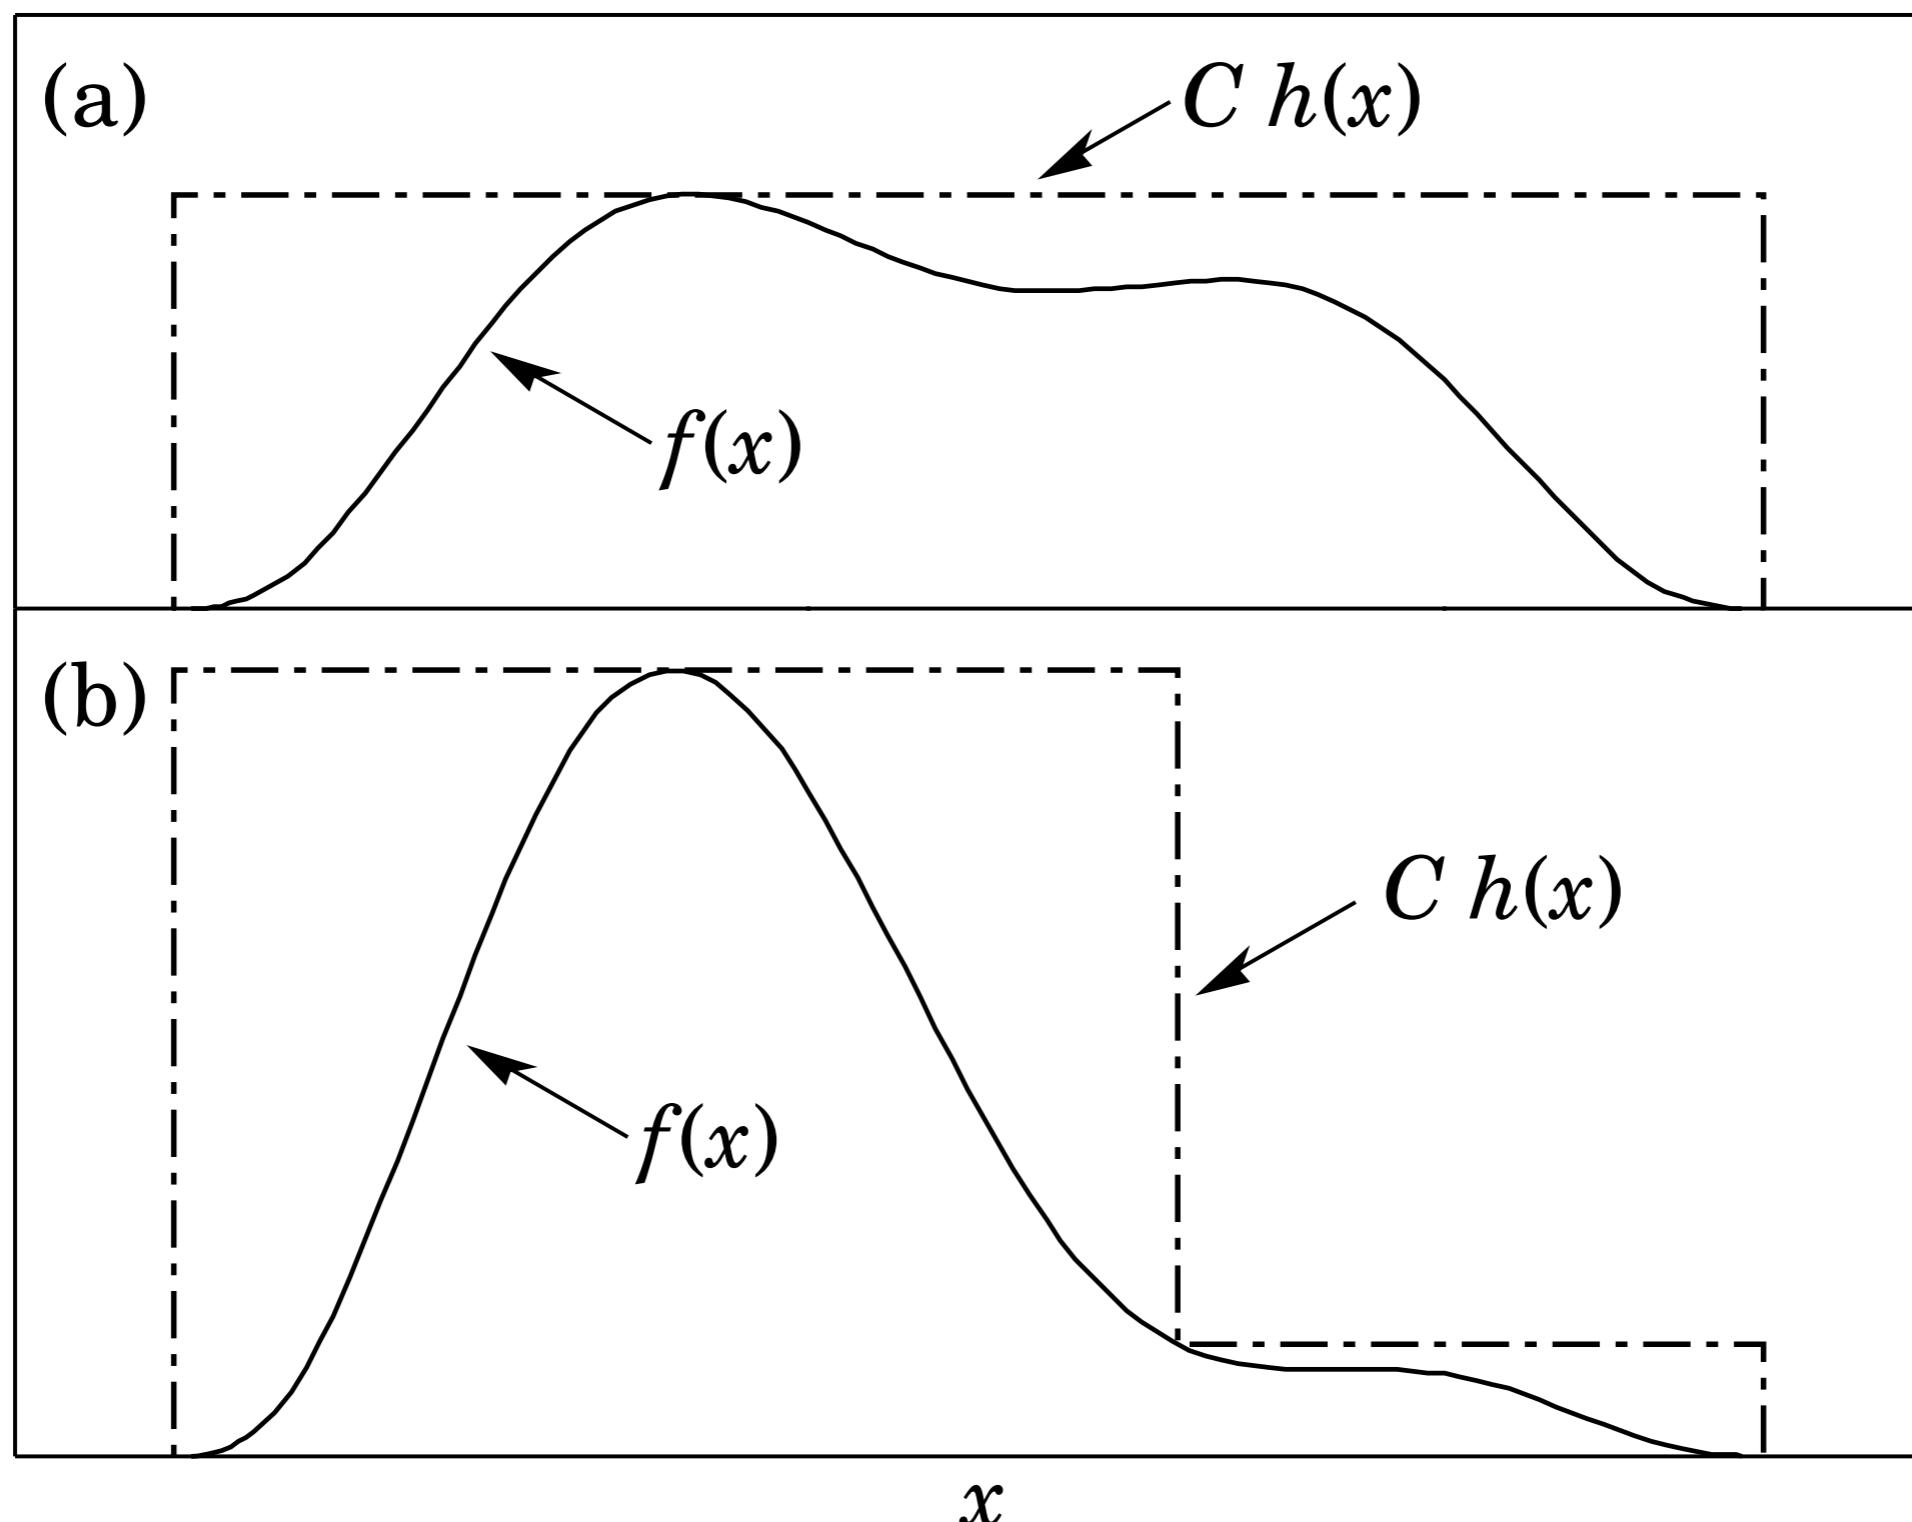

# Example

**Figure 39.1:** Use of a random number  $u$  chosen from a uniform distribution  $(0,1)$  to find a random number  $x$  from a distribution with cumulative distribution function  $F(x)$ .

# Accept-Reject Method

- If  $f(x)$  is an  $\text{expensive}$ , or difficult to compute  $\text{function}$ , then finding  $f(x)$  may be  $\text{difficult}$ .
- Let's suppose however that  $f(x)$  is  $\text{continuous}$  and  $\text{differentiable}$ , such that for any  $x$  we can find an easily generated  $\text{upper bound}$   $M$  and a constant  $c$ .
  - Accept-reject method:
    - Generate  $U$  according to  $U \sim U(0, 1)$ , and
    - If  $U < f(x)/M$ , accept  $x$ ;
    - Otherwise reject  $x$  and generate a new  $x$ .

# Algorithms

- Exponential decay
  - $f(t) =$
  - Generate:  $u \in$  ,  $f(u) =$
  - Define
    - $\alpha =$
    - $\beta =$
  - Then  $t =$
- Gaussian distribution
  - If and are on , then
    - $z_1 =$
    - $z_2 =$
  - are and with mean and  $\sigma =$

# Algorithms

- Poisson Distribution
  - Iterate until a choice
  - Begin with  $k =$  and set  $A =$
  - Generate
  - Replace A with
  - If  $A <$  (where is the parameter)
    - accept  $n_k =$  and
    - Else increment by and generate a new and repeat
    - Always start with the value of left from the

# Applications: MC Integration

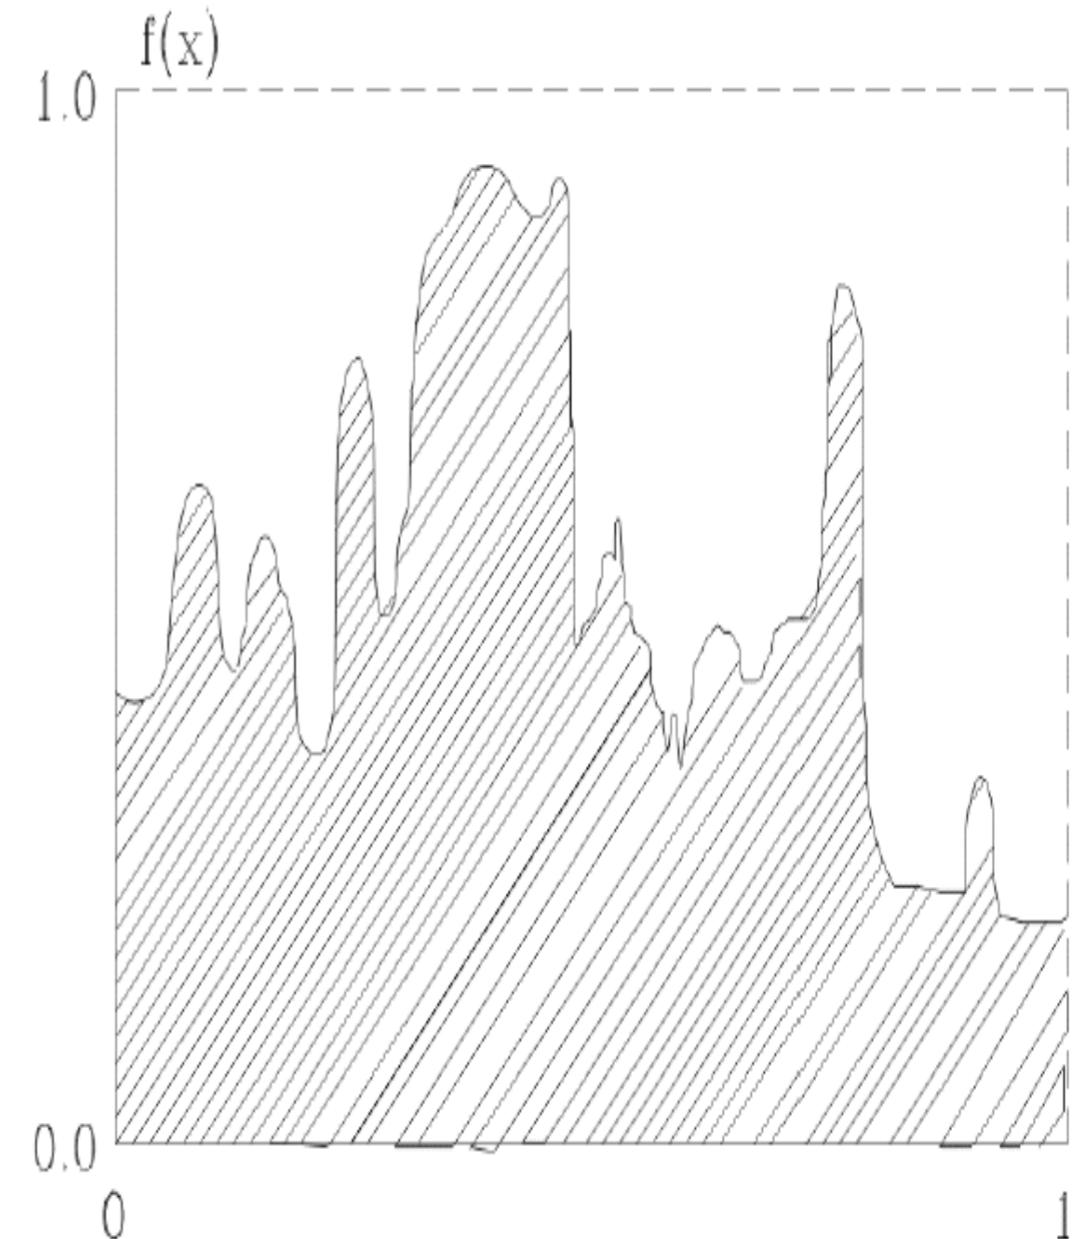

- Suppose we want to compute a

- $Z = \int$

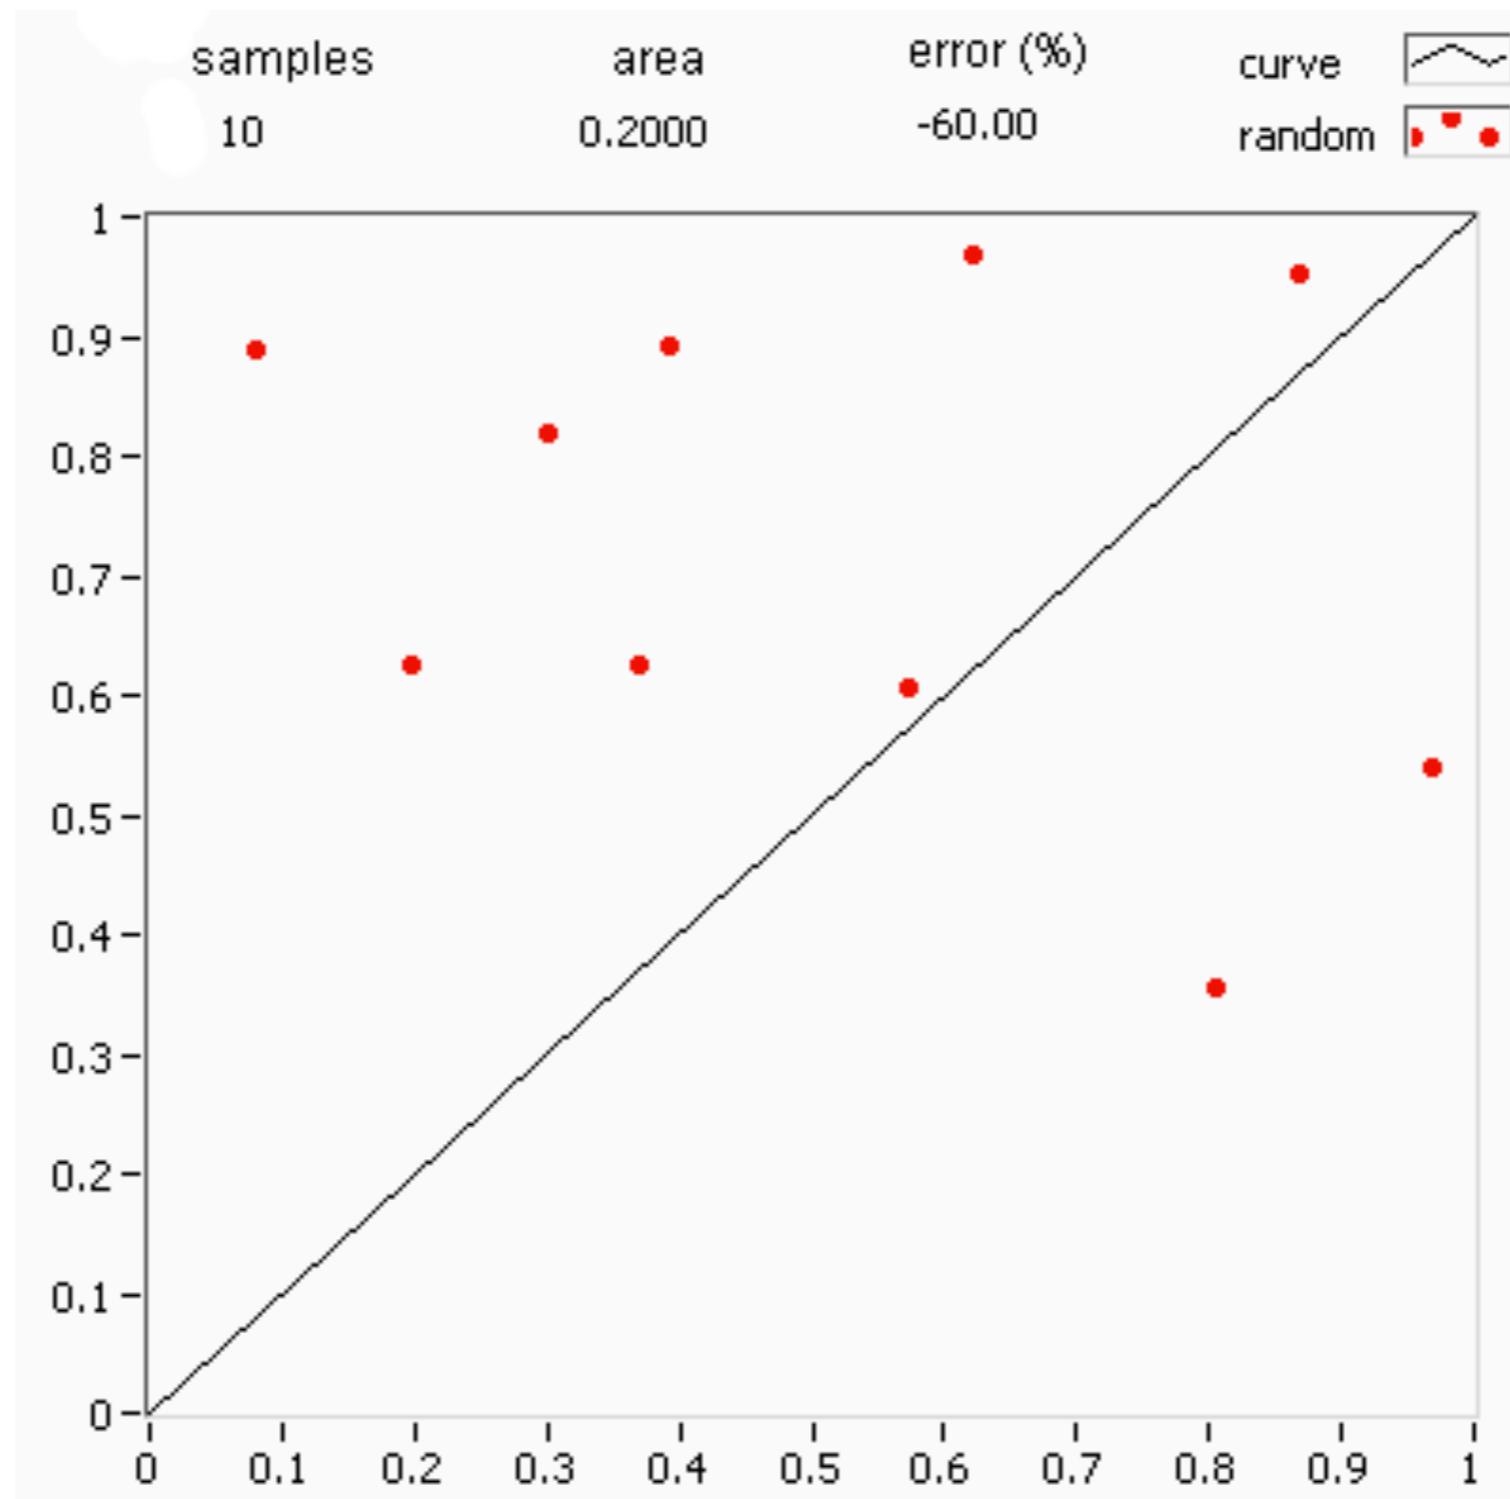

- Generate a  $\mathbf{r}_i$  (e.g. distributed in space )
- If  $\mathbf{r}_i$  is within  $\Omega$ , increment sum
- Repeat  $N$  times
- Uncertainty on  $Z$  typically scales as

# I -dimensional MC

- Suppose we want to find the area under the curve  $y = f(x)$  for a given interval  $[a, b]$ .
- Now let's assume we are at the picture of a function  $f(x)$ .
- Each sample will land on a point  $(x_i, y_i)$ , where  $x_i \sim U(a, b)$  and  $y_i \sim f(x_i)$ .
- If the value of  $y_i > f(x_i)$ , then we count it as a success.
- Repeat the process  $N$  times for a large number of samples.
- The ratio of successes under the curve  $f(x)$  is approximately equal to the area under the curve  $f(x)$ .

# Example

[https://en.wikipedia.org/wiki/Monte\\_Carlo\\_method](https://en.wikipedia.org/wiki/Monte_Carlo_method)

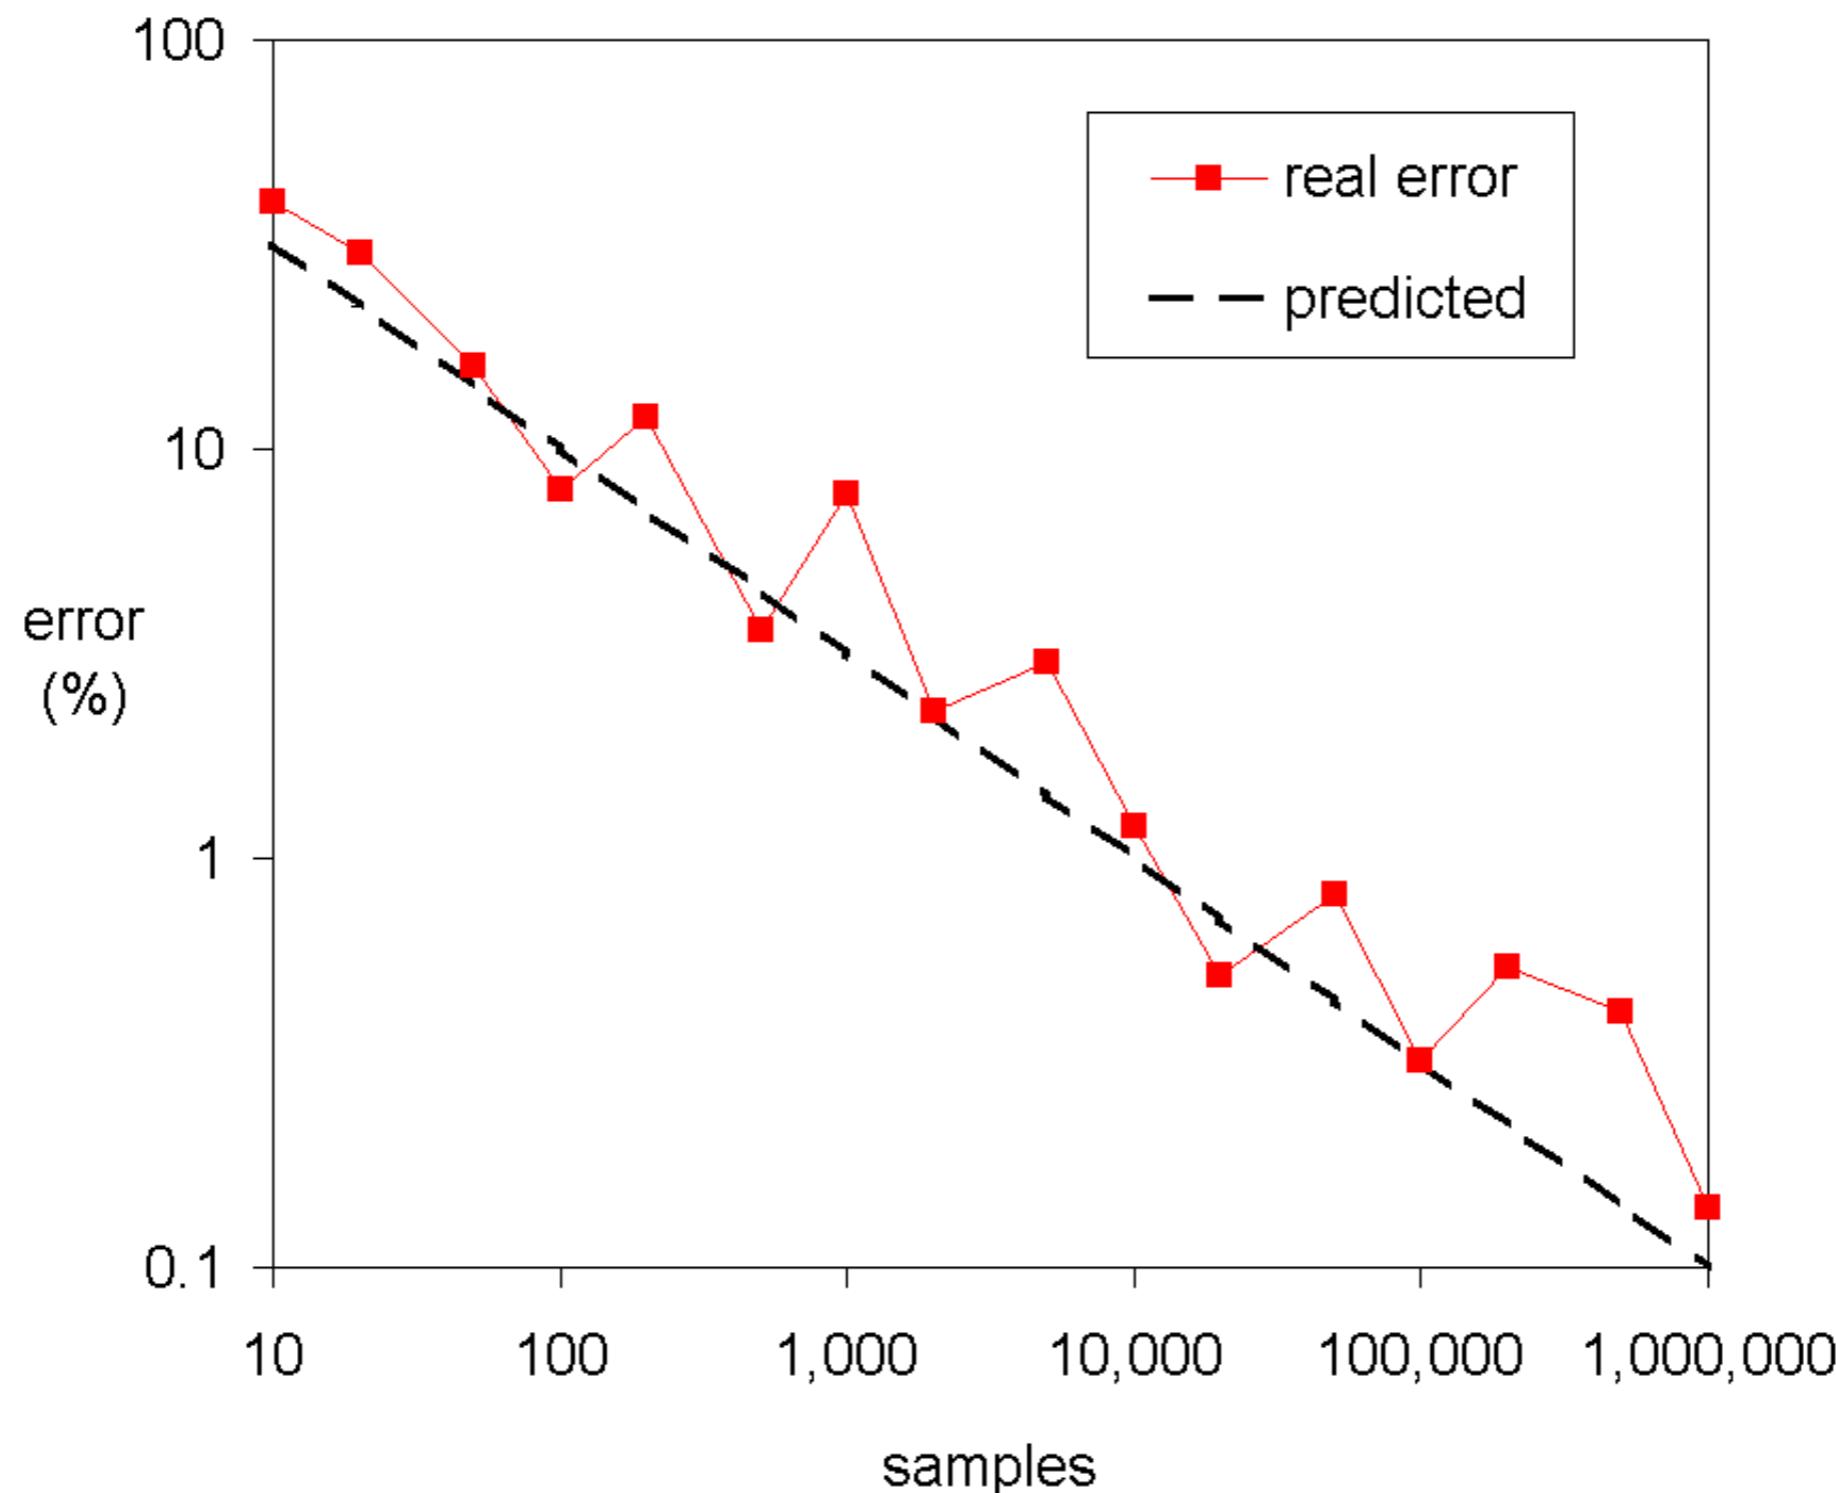

# Error Estimate for MC Integrals

- Uncertainties for follow the distribution
- Let the under the curve be , and the populated by is
- Let be the number of points , and the number of points .
- Then the estimator of is:
  - $\hat{S} =$
- Define the of as
  - $\epsilon =$

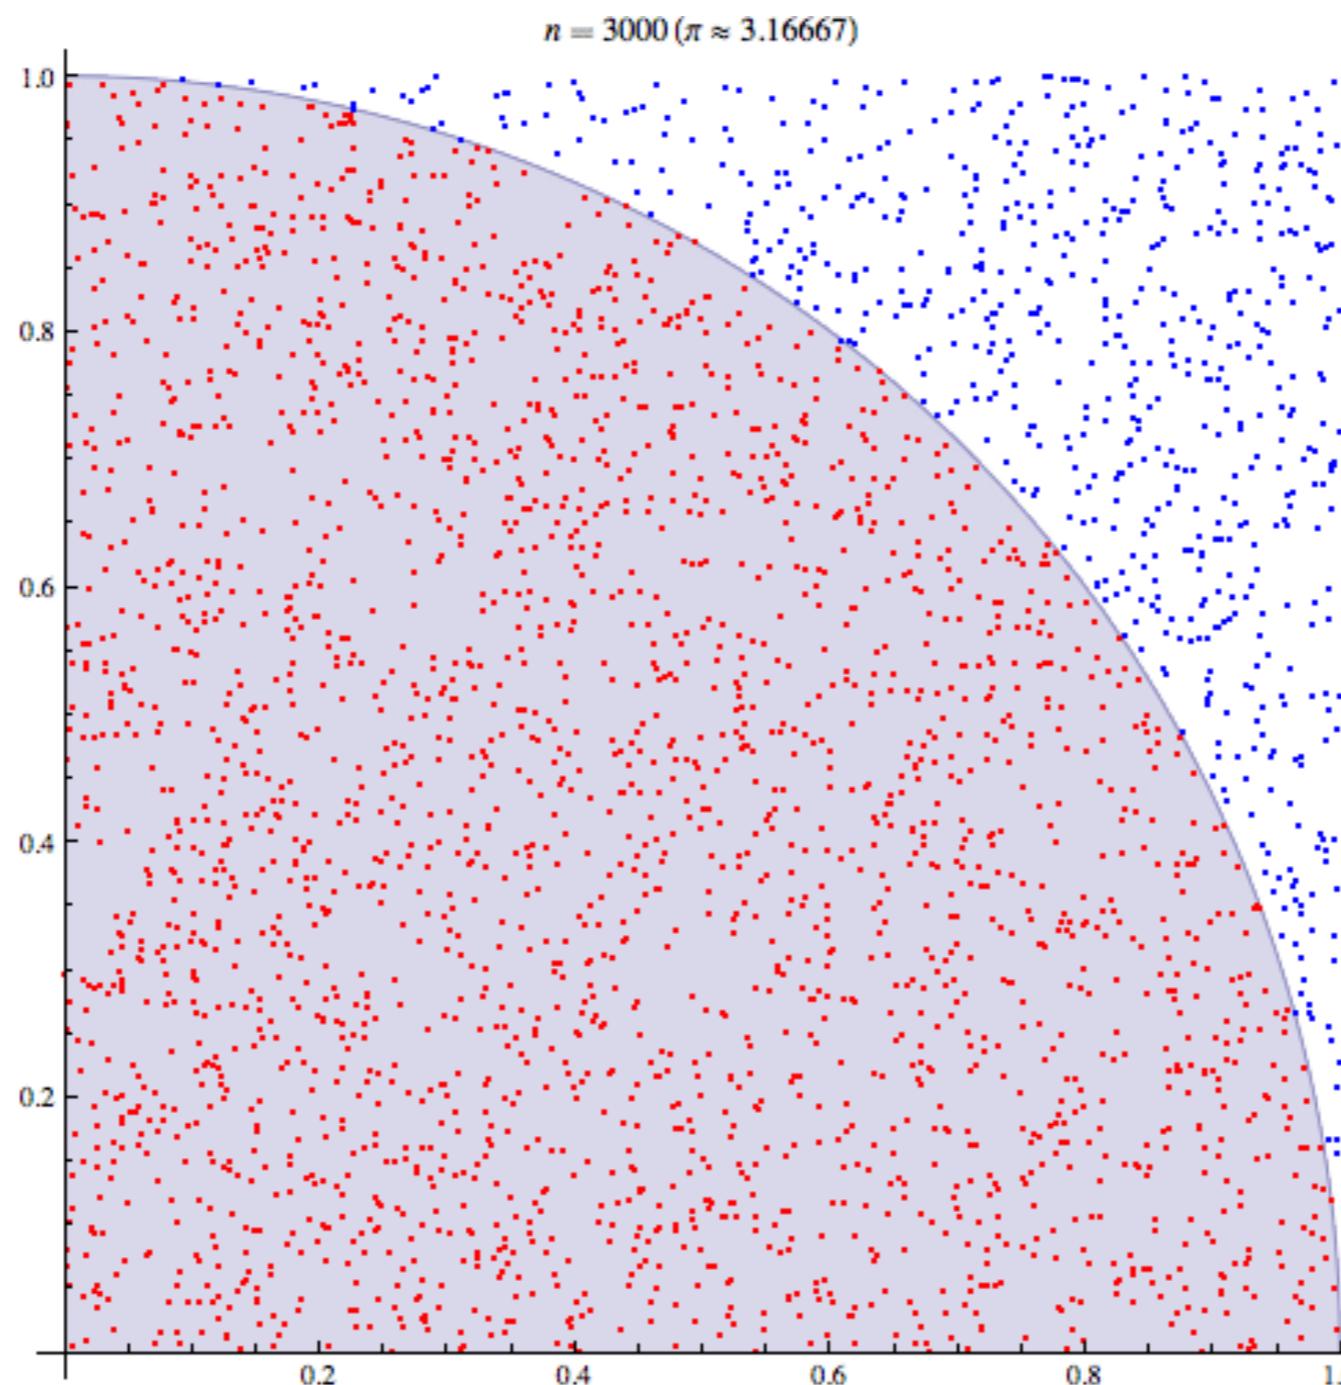

# Error Estimate for MC Integrals

- $\hat{\epsilon}$  is a variable, which follows a distribution (“choose out of ”).
- Estimator of  $S$  is therefore also a random variable.
- Its standard deviation is given by
  - $\sigma(\hat{\epsilon}) = \sqrt{\frac{1}{N} \sum_{i=1}^N (\epsilon_i - \bar{\epsilon})^2}$
  - You can show that in the limit  $N \rightarrow \infty$ ,
    - $\sigma(\hat{\epsilon}) \approx \sqrt{\frac{1}{N} \sum_{i=1}^N \epsilon_i^2 - \bar{\epsilon}^2}$
    - $\sigma(\hat{S}) = \sqrt{\frac{1}{N} \sum_{i=1}^N S_i^2 - \bar{S}^2}$

# Error Estimate

# Example: Compute $\pi$ by MC
